

NCP81063

Synchronous Buck MOSFET Drivers

The NCP81063 is a high-performance dual MOSFET gate driver in a small 3 mm x 3 mm package, optimized to drive the gates of both high-side and low-side power MOSFETs in a synchronous buck converter. A zero-current detection feature allows for a high-efficiency solution even at light load conditions. VCC UVLO ensures the MOSFETs are off when supply voltages are low. A bi-directional Enable pin provides a fault signal to the controller when a UVLO fault is detected.

Features

- Space-efficient 3 mm x 3 mm DFN8 Thermally-enhanced Package
- VCC Range of 4.5 V to 13.2 V
- Integrated Bootstrap Diode
- 5 V 3-stage PWM input
- Zero Current Detect Function Provides Power Saving Operation During Light Load Conditions
- Bi-directional Enable Feature Pulls Enable Pin Low During a UVLO Fault
- Output Disable Control Turns Off Both MOSFETs
- VCC Undervoltage Lockout
- Adaptive Anti-cross Conduction Circuit Protects Against Cross-conduction During FET Turn-on and Turn-off
- Direct Interface to NCP6151 and Other Compatible PWM Controllers
- Thermally Enhanced Package
- These Devices are Pb-Free, Halogen Free/BFR Free and are RoHS Compliant

Typical Applications

- Power Solutions for Notebook and Desktop Systems

Figure 1. Pin Diagram

Figure 2. Block Diagram

Table 1. Pin Descriptions

Pin No.	Symbol	Description
1	BST	Floating bootstrap supply pin for high side gate driver. Connect the bootstrap capacitor between this pin and the SW pin.
2	PWM	Control input: PWM = High → DRVH is high, DRVL is low. PWM = Mid → Zero current detect enabled. Diode emulation mode. PWM = Low → DRVH is low, DRVL is high.
3	EN	3-state input: EN = High → Driver is enabled. EN = Low → Driver is disabled.
4	VCC	Power supply input. Connect a bypass capacitor (0.1 μF) from this pin to ground.
5	DRVL	Low side gate drive output. Connect to the gate of low side MOSFET.
6	GND	Bias and reference ground. All signals are referenced to this node (QFN Flag).
7	SW	Switch node. Connect this pin to the source of the high side MOSFET and drain of the low side MOSFET.
8	DRVH	High side gate drive output. Connect to the gate of high side MOSFET.
9	FLAG	Thermal flag. There is no electrical connection to the IC. Connect to ground plane.

Figure 5. Timing Diagram

APPLICATIONS INFORMATION

The NCP81063 gate driver is a single-phase MOSFET driver designed for driving N-channel MOSFETs in a synchronous buck converter topology.

Low-Side Driver

The low-side driver is designed to drive a ground-referenced low- $R_{DS(on)}$ N-channel MOSFET. The voltage supply for the low-side driver is internally connected to the VCC and GND pins.

High-Side Driver

The high-side driver is designed to drive a floating low- $R_{DS(on)}$ N-channel MOSFET. The gate voltage for the high-side driver is developed by a bootstrap circuit referenced to the SW pin.

The bootstrap circuit is comprised of the integrated diode and an external bootstrap capacitor. When the NCP81063 is starting up, the SW pin is held at ground, allowing the bootstrap capacitor to charge up to VCC through the bootstrap diode. When the PWM input is driven high, the high-side driver will turn on the high-side MOSFET using the stored charge of the bootstrap capacitor. As the high-side MOSFET turns on, the SW pin rises. When the high-side MOSFET is fully turned on, SW will settle to VIN and BST will settle to VIN + VCC (excluding parasitic ringing).

Bootstrap Circuit

The bootstrap circuit relies on an external charge storage capacitor (C_{BST}) and an integrated diode to provide current to the high-side driver. A multi-layer ceramic capacitor (MLCC) with a value greater than 100 nF should be used for C_{BST} .

Power Supply Decoupling

The NCP81063 can source and sink relatively large currents to the gate pins of the MOSFETs. In order to maintain a constant and stable supply voltage, a low-ESR capacitor should be placed near the VCC and GND pins. A MLCC between 1 μ F and 4.7 μ F is typically used.

Undervoltage Lockout

DRVH and DRVL are low until VCC reaches the VCC UVLO threshold, typically 4.35 V. Once VCC reaches this threshold, the PWM signal will control DRVH and DRVL. There is a 200 mV hysteresis on VCC UVLO. There are pull-down resistors on DRVH, DRVL and SW to prevent the gates of the MOSFETs from accumulating enough charge to turn on when the driver is powered off.

Bi-Directional EN Signal

The Enable pin (EN) is used to disable the DRVH and DRVL outputs to prevent power transfer. When EN is above the EN_{HI} threshold, DRVH and DRVL change their states according to the PWM input. A UVLO fault turns on the internal MOSFET that pulls the EN pin towards ground. By connecting EN to the DRON pin of a controller, the

controller is alerted when the driver encounters a fault condition.

Three-State PWM Input

Switching PWM between logic-high and logic-low states will allow the driver to operate in continuous conduction mode as long as VCC is greater than the UVLO threshold and EN is high. The threshold limits are specified in the electrical characteristics table in this datasheet. Refer to Figure 21 for the gate timing diagrams and Table 1 for the EN/PWM logic table.

When PWM is set above PWM_{HI} , DRVL will first turn off after a propagation delay of tpd_{DRVL} . To ensure non-overlap between DRVL and DRVH, there is a delay of $tpdh_{DRVH}$ from the time DRVL falls to 1 V, before DRVH is allowed to turn on.

When PWM falls below PWM_{LO} , DRVH will first turn off after a propagation delay of tpd_{DRVH} . To ensure non-overlap between DRVH and DRVL, there is a delay of $tpdh_{DRVL}$ from the time DRVH – SW falls to 1 V, before DRVL is allowed to turn on.

When PWM enters the mid-state voltage range, PWM_{MID} , DRVL goes high after the non-overlap delay, and stays high for the duration of the ZCD blanking timer and an 80 ns de-bounce timer. Once these timers expire, SW is monitored for zero current detection and pulls DRVL low once zero current is detected.

Thermal Considerations

As power in the NCP81063 increases, it might become necessary to provide some thermal relief. The maximum power dissipation supported by the device is dependent upon board design and layout. Mounting pad configuration on the PCB, the board material, and the ambient temperature affect the rate of junction temperature rise for the part. When the NCP81063 has good thermal conductivity through the PCB, the junction temperature will be relatively low with high power applications. The maximum dissipation the NCP81063 can handle is given by:

$$P_{D(MAX)} = \frac{[T_{J(MAX)} - T_A]}{R_{\theta JA}} \quad (eq. 1)$$

Since T_J is not recommended to exceed 150°C, the NCP81063, soldered on to a 645 mm² copper area, using 1 oz. copper and FR4, can dissipate up to 2.3 W when the ambient temperature (T_A) is 25°C. The power dissipated by the NCP81063 can be calculated from the following equation:

$$P_D = VCC \times \left[(n_{HS} \times Q_{gHS} + n_{LS} \times Q_{gLS}) \times f + I_{standby} \right] \quad (eq. 2)$$

Where n_{HS} and n_{LS} are the number of high-side and low-side FETs, respectively, Q_{gHS} and Q_{gLS} are the gate charges of the high-side and low-side FETs, respectively and f is the switching frequency of the converter.
